Physical Characteristics of New Houses

IC Page, MD Curtis

The work reported here was funded by BRANZ
from the Building Research Levy.

© BRANZ 2011
ISSN: 1179-6197

Preface

This is the first of a series of reports on the physical characteristics of new housing. The data was obtained from BRANZ surveys to builders of new detached houses. The purpose of the surveys is to obtain data on new housing which is not available from official sources. This includes the generic type of materials used by building component, and design information such as number of floors, wind zones, envelope risk matrix scores, stud arrangements, prefabrication and efficiency measures. The data is useful for studies in the fields of sustainability, energy efficiency, durability and engineering.

Acknowledgments

This work was funded by the Building Research Levy.

Note

This report is intended for researchers, Government officials and manufacturers.

Physical Characteristics of New Houses

BRANZ Study Report SR 261 [2011]

IC Page, MD Curtis

Abstract

The amount of official data available on the characteristics of new housing is very limited. Building consents data held by Statistics New Zealand provides information on building type, value and floor area aggregated into territorial authorities. This is valuable data, encompassing a complete record of all consents; however, there is no information available on materials used or housing characteristics beyond the floor area. BRANZ began a survey in 1998 to obtain data on materials used in new housing (and other buildings) and has since compiled a database of approximately 1200 new houses per year. This report contains results from those surveys on the generic materials used in new housing and some of the other physical characteristics of the houses. The aim is to provide information useful to researchers, Government officials and manufacturers.

1. INTRODUCTION

Over 1200 new residential units per year are encompassed in the BRANZ New Dwellings Survey. This survey collects a variety of data on materials used in new housing. Using this data, representative results are able to be collected on the incidence and proportions of many different materials. The components and design features analysed are:

- Claddings
- Framing Types
- House Storeys
- Floor Types
- Floor Joists
- Insulation
- Sustainability Features
- Space Heating Appliances
- Wall Stud Arrangements
- Wind Zones
- E2 Risk Scores
- Double Glazing

2. SUMMARY

Data is shown on market share trends for generic materials used in new housing. The survey used to compile the charts began in 1998 but the regional spread and sample size was not sufficient until 2002, so the charts begin from then. The survey was developed mainly for manufacturers and, to preserve confidentiality, the results are shown in generic categories. Not all components/characteristics have been continuously covered since 2002, so some results are for a shorter period.

3. METHOD

Whats On¹ building consent data is used to obtain a sample of new housing for each period. From this sample, builders or designers of new houses from 31 selected territorial authorities are sent our New Dwelling Survey form. Incentives are offered for completion of the form. The 31 territorial authorities are Auckland, Christchurch, Dunedin, Franklin, Far North, Gisborne, Hutt City, Hamilton, Invercargill, Kapiti, Manukau, Marlborough, Napier, New Plymouth, North Shore, Porirua, Palmerston North, Queenstown, Rodney, Southland, Tauranga, Thames-Coromandel, Tasman,

¹ *Whats On Report* (Monthly). TF Stevens & Co Ltd, Auckland, New Zealand.

Waikato, Waipa, Wellington, Waimakariri, Western Bay of Plenty, Whangarei and Waitakere.

Where applicable, results have been weighted based on consent values to allow for regional building activity.

For wind zones, E2 risk scores and double glazing, only recent data has been used. Therefore, the results displayed are an aggregation of the responses that we have received in the last three quarters, i.e. since the December quarter 2010 for each component.

Average floor areas from the past 9 years have been investigated to determine the accuracy of the following results. Figure 1 shows how the average floor area from our sample data matches up against the average floor area from consent data obtained from Statistics New Zealand. Each point on the chart represents one year of data. Our sample has a slight bias towards larger houses, typically about 4% in most years, less in recent years, but up to 9% (in 2007). Reasons for the bias are not known but may be because some smaller territorial authorities are not surveyed and these may tend to have smaller houses (for a list of surveyed territorial authorities see Figure 6).

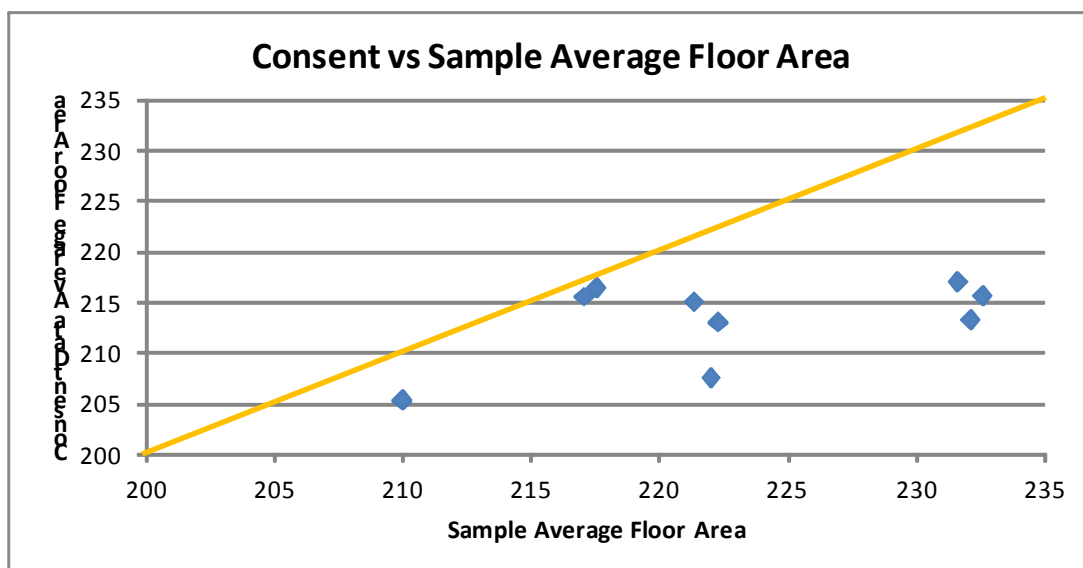

Figure 1 Consent vs Sample Average Floor Area

Figure 2 illustrates the difference between the average consent value and the average survey form value for the houses in our sample. Both follow the same trend throughout the years. The difference between the two is often that builders suggest a lower value in the hope that it will help them obtain a job. Then, once they have the job, the actual cost is sometimes higher. Another reason that may contribute to this difference is that the consent may be applied for before the plan has been finalised, and thus extra costs could be incurred.

Figure 2 Consent vs Survey Average House Value

4. MAIN RESULTS

Further results are shown in the following charts. The data for these charts is provided in the tables in the appendix.

4.1 Roof Claddings

Figure 3 Roof Claddings Market Share

Sheet metal is the dominant roof cladding and is trending upwards. 2005, 2006 and 2008 saw small decreases in the market share for sheet metal. However, overall sheet metal's market share has been increasing.

Tiles are the second-most preferred roof cladding. Combined, metal and concrete tiles hold almost 40% of the market share. Since 2002, concrete tiles have been trending downwards.

4.2 Wall Claddings

Figure 4 Wall Claddings Market Share

Clay brick is the dominant wall cladding, holding over 40% market share throughout the majority of years covered. 2007 and 2008 saw decreases in the market share for clay brick, but it has since recovered slightly.

The Other category, mainly monolithic type claddings (i.e. sheet fibre cement, EIFS and stucco) have trended downwards after the impact of the leaky homes discovery in the early 2000s.

4.3 Wall Frames

Figure 5 Wall Framings Market Share

The wall framing types are shown in Figure 5. Timber framing is the predominant structural material

There has been slow growth in steel framing and solid timber houses since the mid 2000s. Concrete masonry has been fairly steady at around 2-4% market share during the 2000's.

4.4 House Storeys

Figure 6 Multi-Storey Proportion by Territory 2010

Almost 90% of new houses surveyed in Auckland were multi-storeyed in 2010. 65% of new houses in Wellington were multi-storey, the second-highest proportion out of the territories surveyed. No new houses that were surveyed from the Far North were multi-storeyed, the only territory sampled to have 0%.

Figure 7 Floor Area by Storey

Single-storey houses are the most common among new houses. Between 2002 and 2004 multi-storeyed houses gained some prominence, however since then, single-storey houses have gained in share, trending towards 90% of new houses. 2004 and 2005 were highs for more than two storeys, with over 1.5% share. However since then, the share appears to be decreasing.

4.5 Flooring

Figure 8 Flooring Types Market Share

Following a 2008 low for concrete of 73% market share, concrete flooring has risen by 8% to its highest share in the surveyed period. The relative mix of concrete and timber, which includes particleboard, plywood and structural strip timber, floors reflects the type of houses being built.

When larger houses are being constructed on small sections the upper floor proportion (i.e. timber floors) increases. Figure 7 illustrates that after 2004, the proportion of area

in upper storeys decreases, explaining the increase in concrete flooring between 2004 and 2006. The low concrete flooring market share in 2008 was due to a greater proportion of ground floors being made out of timber than in the other years.

4.6 Floor Joists

Figure 9 Floor Joists Market Share

Solid timber floor joists are the most common system for timber floors. However, 2010 saw a decrease in share for timber floor joists, with engineered wood increasing in the same period.

Figure 10 Solid Timber Joist Depths Share 2010

250mm was the most common depth for solid timber joists in 2010. Greater than 5% shares were also seen for 150mm, 200mm and 300mm depths.

4.7 Insulation

Wall insulation, ceiling insulation and floor insulation for both concrete slabs and timber floors have been separated in this section.

4.7.1 Wall Insulation

Figure 11 Wall Insulation Market Share

Fibreglass is by far the most popular wall insulation with over 95% market share in 2010. It is also trending upwards. The “other” category is mainly polystyrene and natural wool.

4.7.2 Ceiling Insulation

Figure 12 Ceiling Insulation Market Share

As with wall insulation, fibreglass dominates the ceiling insulation market. Polyester has closer to 2% market share and wool is the only other notable insulation material.

4.7.3 Floor Insulation

Figure 13 Concrete Floor Insulation Market Share

The percentage of slabs that are insulated has risen steadily and is now about 43%. For those slabs that are insulated, the split is about 50:50 between polystyrene sheet and polystyrene waffle pod type.

Figure 14 Timber Floor Insulation Market Share

Polystyrene floor insulation has gained significant market share in recent years.

4.8 Green Features

Figure 15 Efficiency Devices in New Housing

The above figure illustrates the percentage of new houses having selected energy efficiency and other sustainability items installed. The most common efficiency item during the survey period was dual flush toilets, installed in over 80% of new houses. The average number of items being installed per house was between 2 and 2.5 for most of the period. Sliding vents built into frames are in approximately 10% of windows according to the survey. However, it is possible some respondents have confused the moisture drainage slits in the frame with sliding ventilation openings and the percentage could be over-stated. The questions on efficiency items were removed from the survey in the March quarter 2010 and therefore more recent data is not available.

4.9 Heating Systems

Figure 16 Heating Systems in New Housing

Heat pumps are the preferred heating system in new housing with a 60% market share across the period surveyed. Both gas and wood/pellet burners are the only other heating systems that have been consistently over a 10% share.

4.10 Stud Sizes and Spacing

Figure 17 Stud Sizes and Spacing in New Housing

Over the surveyed period, the 90x45mm @ 600 centres stud size and spacing has remained relatively steady at over 65%. The only other stud size and spacing that has over 5% share is 90x40mm @ 400 centres.

4.11 Downlights

Figure 18 Number of Downlights in New Housing

Figure 18 shows the number of downlights being installed in new housing between February and September 2011. Just over 15% of houses do not have any downlights installed. The greatest proportion is between 21 and 30 downlights.

4.12 Wind Zones

Figure 19 Wind Zones Frequency in New Houses

Wind zone data was collected between September 2010 and June 2011 and the distribution of zones is shown in Figure 19. Note that at the time of the survey the “extra high” wind zone had not been introduced into NZS3604.

Figure 20 Wind Zones by Territory

The windiest territories from those surveyed were Porirua and Wellington. Low wind zones were assigned a value of 1 and very high wind zones were assigned a value of 4, with the average values shown in Figure 20. The higher the wind zone value, the higher the wind zone of the territory.

The majority of responses stated a medium or high wind zone (see Figure 19). This explains the large grouping of territories with average wind zones between 2 and 3 in Figure 20.

The number of responses received is noted in the brackets after the territory and for an average wind zone of 4 to be achieved, as in Porirua, all of the responses must have stated a very high wind zone. The least windy territory was Hamilton with a wind zone of just under 2, meaning that it is between low and medium.

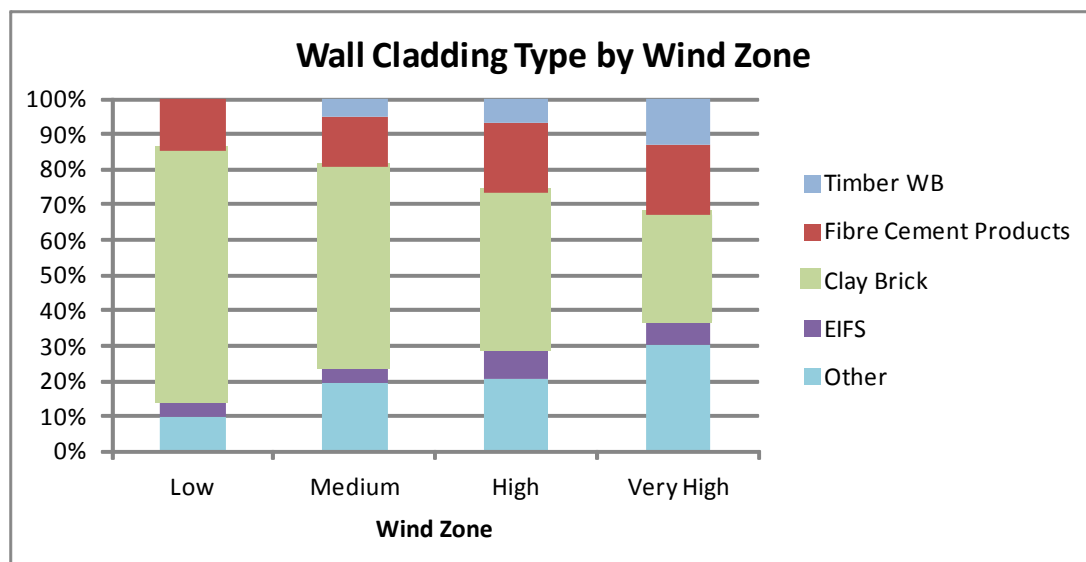

Figure 21 Wall Cladding Type by Wind Zone

Figure 19 shows that there is not a lot of data regarding low and very high wind zones, so data pertaining to the two extremes in Figure 21 should be used with caution. However, there is a definite trend, particularly with the proportion of clay brick wall cladding decreasing in higher wind zones, and both timber weatherboards and “other”, which mainly entails precast slabs, stucco and plaster brick and plywood sheets, increasing.

Figure 22 Roof Slope by Wind Zone

The majority of houses have a roof slope of greater than or equal to 12 degrees across the wind zones. However, with greater wind zones comes an increase in proportion of houses with a roof slope of less than 12 degrees.

4.13 E2 Risk Scores

Average risk scores by territorial authority, from the survey returns, are shown in Figure 23. In the New Zealand Building Code E2 the risk score is a function of wind zone, number of storeys, roof/wall intersection, eaves widths, envelope complexity and decks. The BRANZ survey records the first two factors and part of the envelope complexity. An attempt was made to relate the risk score for each house using the wind zone, number of storeys, number of types of cladding and size of house (floor area) in a regression model. The two latter variables were included to represent envelope complexity, the assumption being larger houses are more likely to have complex layouts than smaller houses.

The results are shown in Figure 24 with the actual score plotted against the predicted score from the model. If the model was accurate, the points would lie on the straight line sloping upwards. As there is a large scatter, the model is not very accurate ($R\text{-squared} = 0.2$).

Figure 23 Average E2 Risk Score by Territorial Authority

Figure 24 Risk Scores – Actual vs Model Prediction

The individual variables do explain some of the risk score as seen between Figure 25 to Figure 27, with the average risk scores increasing as the three factors increase.

Figure 25 Average E2 Risk Score by Number of Storeys

Figure 26 Average E2 Risk Score by Wind Zone

Figure 27 Average E2 Risk Score by Envelope Complexity

4.14 Double Glazing

Figure 28 Double Glazing Rate by Territorial Authority

Double glazing rates from those houses surveyed are generally very high throughout the country. The only areas where it is not 100% are in the upper North Island. They are particularly low in Auckland and the Far North, where fewer than 40% of those new houses surveyed had double glazing for the period between September 2010 and June 2011.

The New Zealand Standard 4218:2009 allows for the use of single-glazing in new housing as long as insulation with greater R-Values is used to produce either the same or less heat loss. The appendix has an analysis of the calculation method and shows it is quite difficult to achieve the required thermal performance in houses below about 180sqm in floor area. This is because small houses have a larger envelope to floor area ratio than larger houses and hence need very large amounts of bulk insulation, and/or a small window area, to compensate for the heat losses through the single

glazed windows. Furthermore, the appendix shows that for typical houses larger than 180sqm the cost trade-offs between single glazing and more insulation, versus less insulation and double glazing, are in favour of the latter using the calculation method in NZS4218, i.e. single glazing is unlikely to be economic.

The only way it could be economic in Auckland and Manukau is to use a fairly refined design using the modelling method. This is discussed in the appendix, where it was found the amount of compensating bulk insulation, with single glazing, is still excessive and remains uneconomic. Some of the Auckland houses with single glazing are in Mount Wellington and Manukau and it is possible the modellers have used Central Auckland climate records (which are incorrect) rather than the general Auckland records. We conclude it is surprising to see single glazing at all in Auckland outside the CBD, whatever the modelling method that has been used.

4.15 Modelling new house costs

New house values in Christchurch and Tauranga were investigated using houses from the survey to see if there is any relationship with various characteristics of the houses. We looked at the floor area, number of storeys, whether it was a timber or concrete ground floor and the number of claddings as variables. A time variable was also added to distinguish between 2009 and 2010 prices. 115 new houses in Christchurch and 129 in Tauranga were sampled.

Christchurch had a better fit than Tauranga to these variables, with many of the relationships being quite strong for Christchurch and weak in Tauranga, often resulting in the opposite happening (i.e. prices in Tauranga between 2009 and 2010 increased whereas in Christchurch they decreased).

The strongest relationship for the builder's value was the floor area variable. In Christchurch, each square metre of floor area added \$1670 to the builder's value of the house and in Tauranga it added \$1470. The next strongest relationship was with the number of storeys. In Christchurch, each extra storey added \$60,230 whereas in Tauranga it added \$58,670. Concrete floors are cheaper than timber floors in Christchurch, where having a concrete floor decreased the cost by \$22,000. However in Tauranga, having a concrete floor increased the cost by \$4500, although it has a much weaker relationship (i.e. a low t-stat). Extra wall claddings added \$13,700 in Christchurch and \$9,900 in Tauranga.

Christchurch regression results 2009-2010			Tauranga regression results	
	Coefficients	T-Stat	Coefficients	T-Stat
Intercept	-100.22	-0.67	-103.65	-0.79
Floor Area	1.67	14.34	1.47	16.74
Number of floors	60.23	3.21	58.67	2.87
Timber or Concrete grd floor	21.75	1.30	-4.42	-0.21
Number of claddings	13.74	1.09	9.94	0.83
Year	-9.69	-0.64	1.10	0.08
R squared	0.78		0.74	
Observations n=	115		129	

Table 1 Builder's Value Data

Coefficients and t-Stat data is listed in Table 1. T-stats values over 2.0 are significant at the 95% confidence level, i.e. we can be 95% confident that the coefficients are

different from zero. So only the floor area and number of floor parameters are statistically significant. Concrete ground floors were assigned the value 1 and timber ground floors were assigned the value 2.

Figure 29 Christchurch House Values

Figure 30 Tauranga House Values

5. CONCLUSIONS

In general, many of the market shares of materials have been relatively steady over the years surveyed. For example, sheet metal roofing and clay brick claddings were the predominate materials over recent years. There are a few exceptions though:

- Concrete structural walls increased their share by 5.5% in 2007 and remained above 10% for the next 2 years before decreasing by 5.5% in 2010.

- The lower proportion of multi-storeyed houses between 2004 and 2006 accounts for the slight increase in concrete share for those years. However, the market share for concrete flooring in 2008 was particularly low due to the larger proportion of timber ground floors picked up by our survey in 2008. Whether this was due to a larger proportion of timber ground floors being built in 2008 than the other years or not is uncertain.
- Solid timber floor joists market share is trending downwards with engineered wood increasing in share.
- The proportion of concrete slabs being insulated is increasing every year.
- Insulation in timber floors has moved towards polystyrene rather than foil.

6. APPENDIX

The appendix contains three items:

- BRANZ New Dwellings Survey details
- Tables of data for the charts
- A cost analysis of insulation and glazing

6.1 BRANZ New Dwellings Survey

This survey has been undertaken since 1998 and was originally developed to obtain data not otherwise available from official or other sources. The main users are building materials manufacturers and the results enable companies to monitor their market share (e.g. claddings and insulation etc). Some questions relate to the layout and design features of new dwellings which are relevant to building officials and researchers, e.g. ground and upper floors, wind zones, envelope risk matrix scores, efficiency measures, heating types, stud sizes and spacings etc. Samples of the forms are shown below. Some questions change from survey to survey but most have remained the same since inception.

It is conducted as a postal survey to the builder identified on the building consent application form and the questions relate to that particular consent. Over 300 returns are received each quarter. The response rate is about 30% and an incentive is offered (Lotto ticket, book voucher or reduced price for BRANZ publications). The main issue is to keep the form as simple and clear as possible and on one page. It is apparent from the density of the form an upper limit on the number of questions has been reached and preferably the form should be simpler to help improve the response rate. At the least, any new questions that might arise from time to time will require the dropping of existing questions. Three survey forms, from between 2006 and 2010, are shown below.

6.3 Cost Analysis of Glazing versus Insulation Trade-offs

After September 2008, a revision to Clause H1 Energy Efficiency of the New Zealand Building Code came into force in Climate Zone 1, i.e. the warmer parts of the country. This revision put double glazing in all new housing in the schedule method. The ability to use the calculation method or the modelling method was retained. Most designers use the schedule method, but it was noted in the survey that after the 2008 change some new houses continued with single glazing. This is permitted if it can be demonstrated that the heat losses are no worse than with the schedule method.

The following describes some analyses done using the calculation method for a range of house sizes and either a square or rectangular floor plan. It compares the heat loss in the building with a reference heat loss. Squarer houses and houses with less glazing area compared to wall area will require less extra insulation to compensate for having single glazing than more rectangular or glazed houses.

Figure 31 assumes a single storey square house with a concrete slab on the ground floor with edge insulation behind the brick veneer, masonry veneer wall cladding and a profiled steel roof. For the purpose of this analysis, 30% glazing area has been assumed. The maximum allowable heat loss increases with the area of the house.

The dark red line illustrates the heat loss if this house was single glazed, with extra insulation to the maximum feasible level for slabs and 90mm timber framed walls. The maximum allowable heat loss is higher than the heat loss line at approximately 155

square metres and therefore, houses less than 155 square metres will either have to reduce the amount of glazing or use double glazing to satisfy the schedule method.

Figure 31 Heat Loss in a Standard Square House Climate Zone 1.

Figure 32 assumes the same as the above. However, instead of a square house, the house is rectangular. The length of the house is assumed to be twice as long as the width. Both the maximum allowable heat loss and heat loss lines are higher as there is now a higher wall-to-floor ratio and thus more glazing.

The minimum area of house required to meet the schedule method is now approximately 175 square metres. All smaller houses will need to reduce the glazing area or use double glazing.

Figure 32 Heat Loss in a Standard Rectangular House Climate Zone 1

These examples indicate it is difficult for typical new housing to avoid double glazing in Climate Zone 1 using the calculation method.

The next part of the analysis entailed examining if the economies of single glazing stack up using the calculation method. Two house sizes were examined, as shown in Table 19.

Table 19 Cost Comparisons of Single vs Double Glazing

Calculation Method:									
220 sqm house									
HL reference	=	$\frac{A_{\text{roof}} + A_{\text{skylight}}}{2.9}$	+	$\frac{A_{70\% \text{ of total wall area}}}{1.9}$	+	$\frac{A_{\text{floor}}}{1.3}$	+	$\frac{A_{30\% \text{ of total wall area}}}{0.26}$

Insul cost \$		2480		1520		0		2576	Total \$ 6576
Calculation method									
Insulation		fibreglass		fibreglass		full cover			
		R5.0		R2.8		100mm EPS		single glaze	
HL =		$\frac{160}{4.35}$	+	$\frac{113.3}{2.2}$	+	$\frac{160}{3.2}$	+	$\frac{32.2}{0.15}$	= 353
Insulation cost\$		4000		3172		3360		0	Total \$ 10532
Roof	Profiled steel -pitched roof, 90mm truss@900ctr (5%)								
Wall	Brick veneer - timber framed 100mm frame, studs 600, dwangs 800 (14%)								
Floor	Slab on Ground - Edge insulation behind brick veneer.								

Schedule Method: Climate Zone 1

Roof	R 2.9
Wall	R 1.9
Floor	R 1.3
Windows and Glazing	R 0.26
Skylights (none)	R 0.26

With single glazing a large amount of bulk insulation is needed to achieve the required heat loss value in both the 200sqm and 160sqm houses. In both houses the single glazed arrangement costs more than the double glazing arrangement. Hence, we conclude single glazing is likely to be uneconomic in Climate Zone 1 using the calculation method.

Finally we investigated the modelling method to ensure that the houses without double glazing, particularly those in Auckland, Manukau and Waitakere, do comply with the building code. We started with a basic and favourable house design in ALF3.2 to determine if it would comply without double glazing in Auckland. Even with a favourable design, extra insulation and decreased window sizes on all sides of the house bar the northern side, we were unable to get the Building Performance Index (BPI) below the $1.55 \text{ kWh}/(\text{m}^2 \cdot ^\circ\text{C month})$ required to comply with the Energy Efficiency Clause H1.

However, the houses we surveyed were not increasing the level of insulation considerably. R-Values of 2.2 for the wall insulation and 3.2 for the ceiling insulation including an insulated concrete slab were standard for the houses surveyed without double glazing.

In an attempt to discover how these houses were complying we looked at ALF3.1. The same house design was input into ALF3.1 and located in Central Auckland. A calculation is available to establish the BPI using ALF3.1. However, it is explicitly stated that "Once the new version is available, ALF3.1 (2000) should not be used for BPI calculations and the method below must NOT be used". Using this method, a BPI of approximately 0.4 is obtained. This is well below the 1.55 needed.

Without increasing the insulation to higher levels than those stated in the survey responses it seems impossible to achieve the required BPI. Also, the houses that are not double glazed do not appear to be in Central Auckland. This is particularly the case for houses in Manukau and Waitakere, but also those located in the former territorial authority of Auckland City appear to be mostly in Mount Wellington rather than Central Auckland.

ALF3.1 has since been removed from the BRANZ website.
